

## Nomenclature for ionic compounds

**Nomenclature** is a system of naming. This worksheet presents a widely used system of nomenclature for ionic compounds.

There are two types of metal cations with different naming conventions discussed separately.

- fixed charge (single charge) cations                      (Never use a Roman numeral)
- variable charge (multiple charge) cations                (Always use a Roman numeral)

### Cations with a single, fixed charge

**Cations** have a positive charge. They are formed from metals, which lie on the left side of the periodic table. The main group (Groups 1-8) metals form cations with a single, fixed charge. The charge is the same as the Group (column) number on the periodic table. The cation name is formed by adding the word “ion” after the element name. For example, the element sodium (Na) is found in Group 1. It ionizes to form the “sodium ion” represented as  $\text{Na}^+$ . The charge is +1 because it is in Group 1.

**Anions** have a negative charge. They are formed from nonmetals, which lie on the right side of the periodic table. The negative charge is found using the **Octet Rule** as eight (8) minus the Group number. Anions always have a single, fixed charge. The anion name is formed by changing the element name suffix to “-ide” and adding the word “ion” after the element name. For example, the element chlorine (Cl) is found in Group 7. It ionizes to form the “chloride ion” represented as  $\text{Cl}^-$ . The charge is -1 because it is in Group 7, and  $8 - 7 = 1$ .

**Ionic compounds** are formed by cation-anion pairs in electrically neutral ratios. They are named using the cation name first, followed by the anion name, excluding the word “ion.” For example, sodium ion ( $\text{Na}^+$ ) and chloride ion ( $\text{Cl}^-$ ) form the compound sodium chloride. Its formula is  $\text{NaCl}$ , which is electrically neutral because sodium ion is +1 and chloride ion is -1. As a second example, magnesium chloride has the formula  $\text{MgCl}_2$ . The subscripts indicate 2 chloride ions ( $\text{Cl}^-$ ) per 1 magnesium ion ( $\text{Mg}^{2+}$ ). The subscript “1” is always implied and never written.

*Note: There is never any charge indicated in the name of a compound having a cation with a single, fixed charge. The single, fixed charge is obvious to a chemist.*

Exercise 1. Provide the name or formula for each ion:

_____	<u>chloride ion</u>	Li <sup>+</sup>	_____
_____	<u>bromide ion</u>	Na <sup>+</sup>	_____
F <sup>-</sup>	_____	K <sup>+</sup>	_____
S <sup>2-</sup>	_____	Mg <sup>2+</sup>	_____
O <sup>2-</sup>	_____	Ca <sup>2+</sup>	_____
N <sup>3-</sup>	_____	Al <sup>3+</sup>	_____
P <sup>3-</sup>	_____	_____	<u>barium ion</u>
C <sup>4-</sup>	_____	_____	<u>boron ion</u>

Exercise 2. Complete the table of neutral ionic compounds with the formulas and names for each cation-anion pair.

	Cl <sup>-</sup>	I <sup>-</sup>	S <sup>2-</sup>	O <sup>2-</sup>	Br <sup>-</sup>	N <sup>3-</sup>
Na <sup>+</sup>						
K <sup>+</sup>						
Mg <sup>2+</sup>						
Al <sup>3+</sup>						

### Cations with a variable/multiple charges

Some transition metals have multiple possible cation charges. A roman numeral (I, II, III, IV, V, ...) must be used in the cation and ionic compound naming system to distinguish between the charges. For example, iron (Fe) can form the iron (II) ion and also the iron (III) ion, denoted Fe<sup>2+</sup> and Fe<sup>3+</sup>, respectively. Iron (II) oxide and iron (III) oxide are distinct compounds, with electrically neutral formulas FeO and Fe<sub>2</sub>O<sub>3</sub>, respectively.

Exercise 3. Provide the formula for each compound.

iron (II) oxide \_\_\_\_\_

iron (III) oxide \_\_\_\_\_

lead (II) chloride \_\_\_\_\_

lead (IV) iodide \_\_\_\_\_

cobalt (II) chloride \_\_\_\_\_

cobalt (III) chloride \_\_\_\_\_

### Mixed cation types

The first step in naming an ionic compound is to determine whether or not the cation can exhibit multiple charges. This requires memorization. Learn the following procedure.

1. The main group (Groups 1-8) elements always have a single charge, determined by the column on the periodic table.
2. Silver and zinc are the only transition metals with a single charge. Memorize the ionic charges for  $\text{Ag}^+$  and  $\text{Zn}^{2+}$ .
3. All other transition metals have multiple charges. Use a roman numeral to indicate the cation charge, which can be figured out from the given information.

Exercise 4. Provide the name for each compound.

$\text{FeO}$  \_\_\_\_\_

$\text{NaCl}$  \_\_\_\_\_

$\text{CuBr}_2$  \_\_\_\_\_

$\text{ZnO}$  \_\_\_\_\_

$\text{K}_3\text{P}$  \_\_\_\_\_

$\text{CaS}$  \_\_\_\_\_

$\text{Ag}_2\text{S}$  \_\_\_\_\_

$\text{CoI}_3$  \_\_\_\_\_

$\text{Be}_3\text{N}_2$  \_\_\_\_\_

## Polyatomic ions

**Polyatomic ions** are charged groups of atoms. An example is ammonium ion,  $\text{NH}_4^+$ . It has five atoms (one nitrogen and four hydrogens) that share a charge of +1. The polyatomic ions remain intact, and parentheses may be required when using subscripts. For example, ammonium chloride is  $\text{NH}_4\text{Cl}$  and ammonium sulfide is  $(\text{NH}_4)_2\text{S}$ . Ammonium is the only polyatomic cation. Common anions are shown in Table 1.

Table 1. Polyatomic ions

Ion name	Ion Formula
ammonium	$\text{NH}_4^+$
cyanide	$\text{CN}^-$
hydroxide	$\text{OH}^-$
perchlorate	$\text{ClO}_4^-$
chlorate	$\text{ClO}_3^-$
chlorite	$\text{ClO}_2^-$
hypochlorite	$\text{ClO}^-$
bromate	$\text{BrO}_3^-$
iodate	$\text{IO}_3^-$
nitrate	$\text{NO}_3^-$
sulfate	$\text{SO}_4^{2-}$
carbonate	$\text{CO}_3^{2-}$
hydrogen carbonate (bicarbonate)	$\text{HCO}_3^-$
phosphate	$\text{PO}_4^{3-}$
hydrogen phosphate	$\text{HPO}_4^{2-}$
dihydrogen phosphate	$\text{H}_2\text{PO}_4^-$
permanganate	$\text{MnO}_4^-$
chromate	$\text{CrO}_4^{2-}$
dichromate	$\text{Cr}_2\text{O}_7^{2-}$
acetate	$\text{C}_2\text{H}_3\text{O}_2^-$ or $\text{CH}_3\text{CO}_2^-$

There are many polyatomic anions. Many occur in **families of names**.

**Start by learning the polyatomic ions ending with “-ate”** such as chlorate ( $\text{ClO}_3^-$ ), nitrate ( $\text{NO}_3^-$ ), sulfate ( $\text{SO}_4^{2-}$ ), carbonate ( $\text{CO}_3^{2-}$ ), and phosphate ( $\text{PO}_4^{3-}$ ).

The corresponding “-ite” ion name has one less oxygen and the same charge. For example, chlorite ion is  $\text{ClO}_2^-$ . Less commonly used names are the “per\_\_-ate” and “hypo\_\_-ite” forms to indicate different numbers of oxygen.

**Key in on the chlorate family in Table 1 to construct names for other ions.** For example, sulfite (not in the table) would be  $\text{SO}_3^{2-}$ , because it has the same charge and one less oxygen than sulfate ( $\text{SO}_4^{2-}$  in the table).

Sometimes “bi-” indicates  $\text{H}^+$  has attached. For example, bicarbonate ( $\text{HCO}_3^-$ ) and carbonate ( $\text{CO}_3^{2-}$ ).

Hydroxide, cyanide, permanganate, acetate, and chromate/dichromate are common polyatomics that do not occur in families.

Exercise 5. Complete the table of neutral ionic compounds with the formulas and names for each cation-anion pair, similar to Exercise 2.

	$\text{SO}_4^{2-}$	$\text{NO}_3^-$	$\text{PO}_4^{3-}$	$\text{CO}_3^{2-}$	$\text{ClO}_3^-$	$\text{OH}^-$
$\text{Na}^+$						
$\text{Al}^{3+}$						
$\text{Ba}^{2+}$						
$\text{NH}_4^+$						
$\text{Cu}^+$						

Exercise 6. Provide the formula for each compound.

- sodium sulfate \_\_\_\_\_
- sodium bisulfate \_\_\_\_\_
- sodium sulfite \_\_\_\_\_
- sodium sulfide \_\_\_\_\_
- copper (I) sulfate \_\_\_\_\_
- copper (II) sulfite \_\_\_\_\_
- copper (II) sulfide \_\_\_\_\_

Exercise 7. Provide the formula for each compound.

- nickel (III) carbonate \_\_\_\_\_
- calcium nitrate \_\_\_\_\_
- copper (II) acetate \_\_\_\_\_
- potassium phosphate \_\_\_\_\_
- silver acetate \_\_\_\_\_
- zinc chromate \_\_\_\_\_
- tin (II) nitrate \_\_\_\_\_
- tin (II) nitrite \_\_\_\_\_
- ammonium bicarbonate \_\_\_\_\_
- copper (II) sulfite \_\_\_\_\_
- sodium hydroxide \_\_\_\_\_
- potassium cyanide \_\_\_\_\_
- potassium phosphide \_\_\_\_\_

Exercise 8. Provide the name for each compound.

- CuCN \_\_\_\_\_
- FeO \_\_\_\_\_
- ZnO \_\_\_\_\_
- Al<sub>2</sub>O<sub>3</sub> \_\_\_\_\_
- AgCl \_\_\_\_\_
- NH<sub>4</sub>NO<sub>3</sub> \_\_\_\_\_
- NaNO<sub>3</sub> \_\_\_\_\_
- NaNO<sub>2</sub> \_\_\_\_\_
- Ca(NO<sub>2</sub>)<sub>2</sub> \_\_\_\_\_
- FeCrO<sub>4</sub> \_\_\_\_\_
